1. Experimental phenomena

1.1 After running the program, you can see the interface as shown below. Click the color button below to select a color, and the video screen will display the color you selected.
1.2 When the color(you choose) block appears in the video, the robotic arm will calculate the position of the block.

1.3 When the area of the block in the video becomes smaller, the robotic arm will drive forward until the front end completes the grasping action. When the area of the block in the video becomes larger, the robotic arm will move back and shake its head.

2. About code

2.1 Using polygonal approximation method to obtain the area of color objects in the field of view

```
for i, cnt in enumerate(contours):

    mm = cv.moments(cnt)
    if mm['m00'] == 0:
    continue
    cx = mm['m10'] / mm['m00']
    cy = mm['m01'] / mm['m00']
    area = cv.contourArea(cnt)
```

2.2 Get the current position and posture through positive solutions

```
def get_Posture(self):
    self.read_joint()
    self.client.wait_for_service()
```

```
request = kinemaricsRequest()
... ...
```

2.3 Estimate location based on area of block in video

```
distance = 27.05 * math.pow(area, -0.51) - 0.2
target_dist = distance + self.Posture[1]
```

2.4 Find the angle that each servo needs to turn

```
def snake_run(self, point_y):
    pass
```

2.5 Inverse design

```
///////////////   Catch game   ///////////////
if (request.tar_z >= 0.2) {
    x=request.tar_x;
    y=request.tar_y;
    z=request.tar_z;
    Roll= -90;
}
```
